# An old story: Rumer, Teller and Weyl (1932)

500

G. RUMER, E. TELLER und H. WEYL,

2. Fundamentalsatz: Alle linearen Abhängigkeiten zwischen den Monomen ergeben sich (in einem algebraisch genauer präzierten Sinne) aus der einen Identität (2).

Wir werden uns hier auf den ersten, nicht aber auf den zweiten Fundamentalsatz stützen; vielmehr wird durch unsere Überlegungen ein neuer Beweis des 2. Fundamentalsatzes erbracht.

In der Quantenmechanik bedeuten die Zeichen  $x, y, \dots, z$  Atome, die sich zu einem Molekül zusammensetzen,  $a, b, \dots, c$  deren Valenzen. Jede Invariante der geforderten Ordnung stellt einen Spinzustand des Moleküls dar. Die durch die Monome repräsentierten „reinen Valenzzustände“ veranschaulicht sich der Chemiker durch ein Valenzschema, in dem die Atome als Punkte erscheinen und jeder Klammerfaktor  $[xy]$  durch einen die beiden Atome  $x$  und  $y$  verbindenden gerichteten Strich zum Ausdruck gebracht wird.  $a, b, \dots, c$  sind dann die Anzahlen der Valenzstriche, die von den einzelnen Atomen  $x, y, \dots, z$  im Valenzschema des Monoms ausgehen. Man zeichne die Punkte  $x, y, \dots, z$  auf einem Kreise auf. Die zu beweisende Regel lautet dann:

Jede Invariante  $J$  ist eine lineare Kombination solcher Monome, deren Valenzschema keine sich kreuzenden Valenzstriche enthält. Die Monome mit kreuzungslosem Valenzschema sind aber linear unabhängig von einander.

Beim Beweise des ersten Teils kann man nach dem 1. Fundamentalsatz annehmen, daß die Invariante  $J$  ein Monom ist, welches wir durch sein Valenzschema  $S$  abbilden. Es bestehe aus  $N$  Strichen zwischen den  $n$  Punkten  $x, y, \dots, z$ . Wir stützen uns darauf, daß man mit Hilfe der Relation (2):

$$(3) \quad \begin{array}{c} x \\ \circ \\ \diagdown \quad \diagup \\ \circ \quad \circ \\ y \quad z \\ \diagup \quad \diagdown \\ \circ \quad \circ \\ p \quad q \end{array} = \begin{array}{c} \circ \quad \circ \\ \hline \circ \quad \circ \end{array} + \begin{array}{c} \circ \\ | \\ \circ \end{array} \quad \begin{array}{c} \circ \\ | \\ \circ \end{array}$$

Kreuzungen auflösen kann<sup>1)</sup>. Natürlich ist mit dieser Bemerkung nicht alles getan; denn wenn man in einem komplizierten Schema die Kreuzung zweier Valenzstriche auflöst, werden dadurch im allgemeinen andere Kreuzungen teils mit aufgelöst, teils neu entstehen. Dennoch kommt man durch ein geeignetes rekursives Arrangement zum Ziel, wie folgt.

1) In der Figur wurde der Richtungssinn der Valenzstriche weggelassen.

# The $\mathfrak{sl}_2$ -webs

## Definition (Rumar, Teller, Weyl 1932)

Fix two numbers  $b, t \in \mathbb{N}$  with  $b + t = 2\ell$ . A  $\mathfrak{sl}_2$ -web  $w$  with  $b$  bottom points and  $t$  top points is an embedding (non-intersecting!) of a finite number of lines and circles in a rectangle with  $b$  fixed points at the bottom and  $t$  at the top such that the two boundary points of the lines are some of the fixed points. The set of all  $\mathfrak{sl}_2$ -webs  $w$  between  $b$  bottom points and  $t$  top points is denoted by  $\tilde{W}_2(b, t)$ .

## Example ( $b = 3$ and $t = 5$ )

# The $\mathfrak{sl}_2$ -web space

## Definition

Fix two numbers  $b, t \in \mathbb{N}$  with  $b + t = 2\ell$ . The  $\mathfrak{sl}_2$ -web space  $W_2(b, t)$  is the free  $\mathbb{Q}(q)$ -vector space generated by elements of  $\tilde{W}_2(b, t)$  modulo

- The circle removal

$$\bigcirc = [2] = q + q^{-1}$$

- The isotopy relations

The diagram shows three diagrams connected by equals signs. The first diagram is a strand that starts on the left, goes up, forms a hump, goes down, forms a dip, goes up, and ends on the right. The second diagram is a vertical straight strand. The third diagram is a strand that starts on the left, goes down, forms a dip, goes up, forms a hump, goes down, and ends on the right.

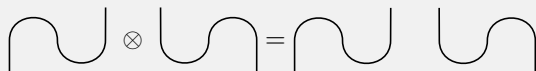

Note that  $W_2(b, t)$  is a finite dimensional  $\mathbb{Q}(q)$ -vector space!

# The $\mathfrak{sl}_2$ -web category

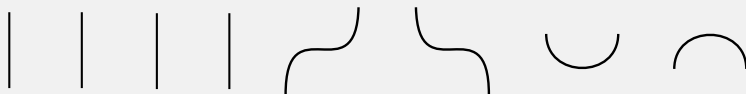

## Definition (Kuperberg 1997)

The  $\mathfrak{sl}_2$ -web category or web spider  $\mathbf{Sp}(\mathbf{U}_q(\mathfrak{sl}_2))$  is the monoidal,  $\bar{\mathbb{Q}}(q)$ -linear 1-category consisting of

- The **objects** are the natural numbers  $\mathbb{N} = \{0, 1, 2, \dots\}$ .
- The **1-cells**  $w: b \rightarrow t$  are the elements of  $W_2(b, t)$ .
- The  $\bar{\mathbb{Q}}(q)$ -linear composition is **stacking**.
- The monoidal structure  $\otimes$  is given by **juxtaposition**, i.e.  $b \otimes b' = b + b'$  and

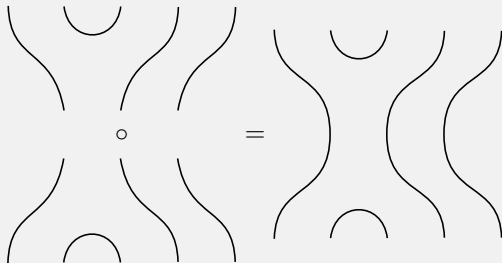

$$\text{wavy line} \otimes \text{wavy line} = \text{wavy line} \text{ stacked over wavy line}$$

- As generators **suffices** the identities, shifts, cups and caps

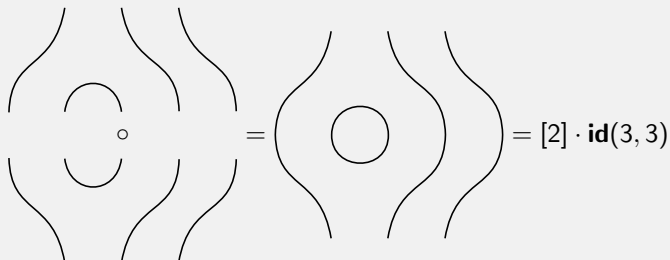

# The $\mathfrak{sl}_2$ -web category - examples

## Example

and

# An extra information

## Definition

Given a  $\mathfrak{sl}_2$ -web  $w \in W_2(b, t)$ . A  $\mathfrak{sl}_2$ -flow line  $f$  for  $w$ , denoted by  $w_f$ , is a choice of orientation for all lines and circles of  $w$ .

If one ignores internal circles

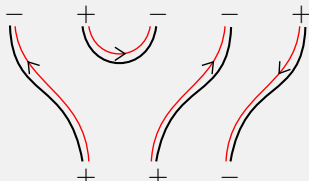

and

then such a flow line is **completely** determine by its boundary. There it induces a **state string** for the bottom  $\vec{S}_b = (\pm, \dots, \pm)$  and top  $\vec{S}_t = (\pm, \dots, \pm)$  with a plus for outgoing flow lines and a minus for incoming.

## Example

# The weight of a flow

## Definition

Flows on the generators of the  $\mathfrak{sl}_2$ -web category  $\mathbf{Sp}(\mathbf{U}_q(\mathfrak{sl}_2))$  are assigned a certain **weight wt** by the local rules

$$\text{wt}(\text{downward flow}) = 0 \quad \text{wt}(\text{upward flow}) = -1 \quad \text{wt}(\text{downward flow with top arc}) = 0 \quad \text{wt}(\text{downward flow with bottom arc}) = +1$$

and always zero on identities and shifts. The **weight** of any  $\mathfrak{sl}_2$ -web with flow is the sum over the local weights.

Note that the weight is **isotopy invariant**, thus, **well-defined** for  $\mathfrak{sl}_2$ -webs without internal circles.

## Example

The diagram illustrates the isotopy invariance of the weight for a crossing. It shows three equivalent configurations of a crossing with flow lines:

- Left configuration: A crossing with a top arc (labeled  $\text{wt}=+1$ ) and a bottom arc (labeled  $\text{wt}=-1$ ). The total weight is  $\text{wt} = 0$ .
- Middle configuration: A crossing with no arcs (labeled  $\text{wt} = 0$ ).
- Right configuration: A crossing with a bottom arc (labeled  $\text{wt}=0$ ) and a top arc (labeled  $\text{wt}=0$ ). The total weight is  $\text{wt} = 0$ .

The configurations are connected by equals signs, indicating they are isotopic and share the same weight.

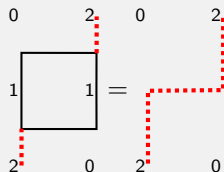

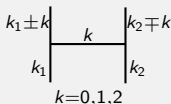

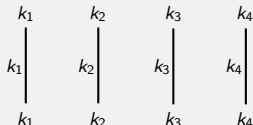

# Rigidity of $\mathfrak{sl}_2$ -webs

A seemingly very small point turned out to be a **crucial step** if we want to consider bigger  $n$ : Topology is continuous and Algebra is rigid.

## Definition, second try - rigid version

The  $\mathfrak{sl}_2$ -web category or web spider  $\mathbf{Sp}(\mathbf{U}_q(\mathfrak{sl}_2))$  is the monoidal,  $\bar{\mathbb{Q}}(q)$ -linear 1-category consisting of

- The **objects** are ordered compositions  $\vec{k}$  of  $2\ell \in \mathbb{N}$  with only  $0, 1, 2$  as entries.
- The **1-cells**  $w: \vec{k} \rightarrow \vec{k}'$  are **labelled ladders** (we use the convention and do not draw edges labelled  $0$  and use a dotted line for those labelled  $2$ ) generated by juxtaposition and vertical composition of (plus relations and rest **as before**)

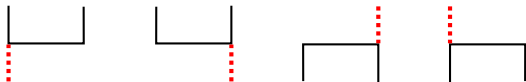

What is the **upshot**? “Easy” to generalize to  $\mathfrak{sl}_n$ : Take labels  $0, 1, \dots, n-1, n$  and “directly” connected to the algebra (which I explain in a second!).

# A rigid example

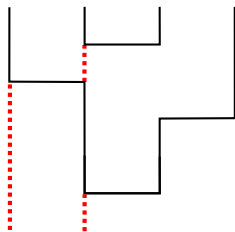

There is a small number of different ladders, namely the **left and right shifts**

and (rigid) **cups and caps**

These suffice to generate all  $\mathfrak{sl}_2$ -webs, e.g.

# The quantum algebra $\mathbf{U}_q(\mathfrak{sl}_d)$

## Definition

For  $d \in \mathbb{N}_{>1}$  the **quantum special linear algebra**  $\mathbf{U}_q(\mathfrak{sl}_d)$  is the associative, unital  $\bar{\mathbb{Q}}(q)$ -algebra generated by  $K_i^{\pm 1}$  and  $E_i$  and  $F_i$ , for  $i = 1, \dots, d-1$ , subject to some relations (that we do not need today).

## Definition (Beilinson-Lusztig-MacPherson)

For each  $\vec{k} \in \mathbb{Z}^{d-1}$  adjoin an **idempotent**  $1_{\vec{k}}$  (**think**: projection to the  $\vec{k}$ -weight space!) to  $\mathbf{U}_q(\mathfrak{sl}_d)$  and add some relations, e.g.

$$1_{\vec{k}} 1_{\vec{k}'} = \delta_{\vec{k}, \vec{k}'} 1_{\vec{k}} \quad \text{and} \quad K_{\pm i} 1_{\vec{k}} = q^{\pm \vec{k}_i} 1_{\vec{k}} \quad (\text{no } K' \text{'s anymore!}).$$

The **idempotent quantum special linear algebra** is defined by

$$\dot{\mathbf{U}}_q(\mathfrak{sl}_d) = \bigoplus_{\vec{k}, \vec{k}' \in \mathbb{Z}^{d-1}} 1_{\vec{k}} \mathbf{U}_q(\mathfrak{sl}_d) 1_{\vec{k}'}$$

# The quantum algebra $\mathbf{U}_q(\mathfrak{sl}_d)$ is a Hopf algebra

It is worth noting that  $\mathbf{U}_q(\mathfrak{sl}_d)$  is a Hopf algebra with coproduct  $\Delta$  given by

$$\Delta(E_i) = E_i \otimes K_i + 1 \otimes E_i, \quad \Delta(F_i) = F_i \otimes 1 + K_i^{-1} \otimes F_i \quad \text{and} \quad \Delta(K_i) = K_i \otimes K_i.$$

The antipode  $S$  and the counit  $\varepsilon$  are given by

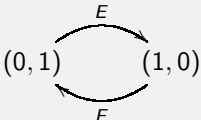

$$S(E_i) = -E_i K_i^{-1}, \quad S(F_i) = -K_i F_i, \quad S(K_i) = K_i^{-1}, \quad \varepsilon(E_i) = \varepsilon(F_i) = 0, \quad \varepsilon(K_i) = 1.$$

The Hopf algebra structure allows to extend actions to tensor products of representations, to duals of representations and there is a trivial representation.

## Example: $\mathbf{U}_q(\mathfrak{sl}_2)$ -vector representation

Consider  $\bar{\mathbb{Q}}^2$  with basis  $x_{-1} = (0, 1)$ ,  $x_{+1} = (1, 0)$ . These are called the weights  $-1$  and  $+1$  and  $K$  acts on them by  $q^{\mp 1}$ . The vector representation of  $\mathbf{U}_q(\mathfrak{sl}_2)$  is:

Think:  $K = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$

Think:  $E = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$

$F = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$

# The category $\mathbf{Rep}(\mathbf{U}_q(\mathfrak{sl}_2))$

## Definition

The **representation category**  $\mathbf{Rep}(\mathbf{U}_q(\mathfrak{sl}_2))$  is the monoidal,  $\bar{\mathbb{Q}}(q)$ -linear 1-category consisting of:

- The **objects** are finite tensor products of the  $\mathbf{U}_q(\mathfrak{sl}_2)$ -representations  $\Lambda^k \bar{\mathbb{Q}}^2$ . Denote them by  $\vec{k} = (k_1, \dots, k_m)$  with  $k_i \in \{0, 1, 2\}$ .
- The **1-cells**  $w: \vec{k} \rightarrow \vec{k}'$  are  $\mathbf{U}_q(\mathfrak{sl}_2)$ -intertwiners.
- Composition of 1-cells is **composition of intertwiners** and  $\otimes$  is the **ordered tensor product**.

It is worth noting that  $\Lambda^0 \bar{\mathbb{Q}}^2 = \bar{\mathbb{Q}}$  is the trivial  $\mathbf{U}_q(\mathfrak{sl}_2)$ -representation,  $\Lambda^2 \bar{\mathbb{Q}}^2 \cong \bar{\mathbb{Q}}$  its dual and  $\Lambda^1 \bar{\mathbb{Q}}^2 = \bar{\mathbb{Q}}^2$  is the (self-dual)  $\mathbf{U}_q(\mathfrak{sl}_2)$ -vector representation.

## Example

The 1-cells of  $\mathbf{Mor}(\vec{k}, \vec{k}')$  “are” (using the Hopf algebra structure!) the invariant tensors  $\mathbf{Inv}_{\mathbf{U}_q(\mathfrak{sl}_2)}(\vec{k}^* \otimes \vec{k}')$  with  $\vec{k}^* = (2 - k_1, \dots, 2 - k_m)$ .

# We have some control over the intertwiner

Given  $V = \bigotimes_i \Lambda^{k_i} \bar{\mathbb{Q}}^2$  denote the **tensor basis** of  $V$  (recall  $x_{-1} = (0, 1)$  and  $x_{+1} = (1, 0)$ , set  $x_\emptyset = x_{\{-1, +1\}} = 1$ ) by  $\{x_S \mid S = (S_1, \dots, S_m), S_i \subset \{-1, +1\}\}$ .

**Theorem (Kuperberg 1997,  $n > 3$ : Cautis-Kamnitzer-Morrison 2012)**

Define two  $\bar{\mathbb{Q}}$ -linear maps called **split and merge** by

$$M_s^{a,b}: \Lambda^{a+b} \bar{\mathbb{Q}}^2 \rightarrow \Lambda^a \bar{\mathbb{Q}}^2 \otimes \Lambda^b \bar{\mathbb{Q}}^2, \quad M_s^{a,b}(x_S) = \sum_{T \subset S} (-q)^{\ell(S,T)} x_T \otimes x_{S-T}$$

$$M_m^{a,b}: \Lambda^a \bar{\mathbb{Q}}^2 \otimes \Lambda^b \bar{\mathbb{Q}}^2 \rightarrow \Lambda^{a+b} \bar{\mathbb{Q}}^2, \quad M_m^{a,b}(x_S \otimes x_T) = \begin{cases} (-q)^{-\ell(T,S)} x_{S \cup T}, & S \cap T = \emptyset, \\ 0, & \text{else.} \end{cases}$$

for suitable  $a, b \in \{0, 1, 2\}$  and  $\ell(S, T) \in \{-1, 0, +1\}$ . These are  **$U_q(\mathfrak{sl}_2)$ -intertwiner** and **generate  $\text{Rep}(U_q(\mathfrak{sl}_2))$** .

E.g.:  $M_m^{1,1}(x_{-1} \otimes x_{+1}) = (-q)^0$ ,  $M_m^{1,1}(x_{+1} \otimes x_{-1}) = (-q)^{-1}$ ,  $M_m^{1,1}(x_{\pm 1} \otimes x_{\pm 1}) = 0$ .

## Theorem (Kuperberg 1997, $n > 3$ : Cautis-Kamnitzer-Morrison 2012)

The 1-categories  $\mathbf{Rep}(\mathbf{U}_q(\mathfrak{sl}_2))$  and  $\mathbf{Sp}(\mathbf{U}_q(\mathfrak{sl}_2))$  are **equivalent**. To be more precise, the equivalence  $\Gamma: \mathbf{Rep}(\mathbf{U}_q(\mathfrak{sl}_2)) \rightarrow \mathbf{Sp}(\mathbf{U}_q(\mathfrak{sl}_2))$  is given by:

- One objects: Send  $\bigotimes_{\vec{k}} \Lambda^{k_i} \bar{\mathbb{Q}}^2$  to  $\vec{k}$ .
- One 1-cells: We only need to consider the generators split  $M_s^{a,b}$  and merge  $M_m^{a,b}$ . Send them to

$$M_s^{a,b} \mapsto \begin{array}{c} a \\ | \\ \hline b \\ | \\ a+b \\ | \\ 0 \end{array} \quad \text{and} \quad M_m^{a,b} \mapsto \begin{array}{c} 0 \\ | \\ \hline a \\ | \\ a \\ | \\ b \end{array} \begin{array}{c} a+b \\ | \\ b \end{array}$$

- Check that it is **well-defined!**

I am **lying** a little bit: One has to be a little more careful with objects and duals, but we **ignore** this for today.

# Intertwiner are pictures: Some examples

## Exempli gratia

What about the “left-plus-ladders”? They are a **composite!**

# How to prove it? Quantum skew Howe duality!

## Theorem

There is an  $\dot{\mathbf{U}}_q(\mathfrak{sl}_d)$ -action on  $\mathbf{Sp}(\mathbf{U}_q(\mathfrak{sl}_2))^d$  (objects of length  $d$ )!

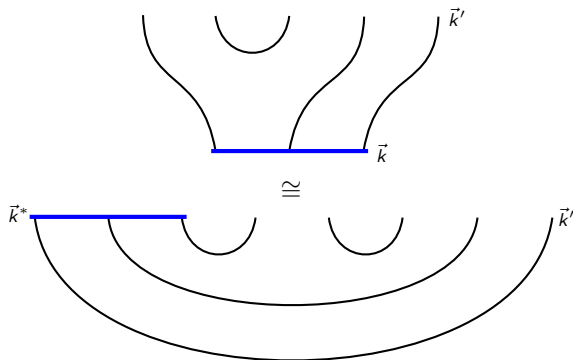

Thus,  $\mathbf{Sp}(\mathbf{U}_q(\mathfrak{sl}_2))^d$  is a  $\dot{\mathbf{U}}_q(\mathfrak{sl}_d)$ -module and **not just** a  $\mathbf{U}_q(\mathfrak{sl}_2)$ -module.

Even better: Since, we **only** need “left-minus-ladders”, aka  $F$ 's, it can be realized as a  $\dot{\mathbf{U}}_q(\mathfrak{sl}_d)$ -module of a certain highest weight: We can **use**  $\dot{\mathbf{U}}_q(\mathfrak{sl}_d)$ -highest weight theory to prove statements about  $\mathbf{U}_q(\mathfrak{sl}_2)$ -intertwiner!

# The invariant tensors suffice - a picture

The Hopf-structure says:  $\mathbf{Mor}(\vec{k}, \vec{k}') \cong \mathbf{Inv}_{\mathbf{U}_q(\mathfrak{sl}_2)}(\vec{k}^* \otimes \vec{k}')$ . The picture says:

Remaining question: How to **identify** the invariant tensors?

# This is not trivial...

First question: What do we **mean** by “identify” the invariant tensors?

$$\text{Recall: } \mathbf{Inv}_{\mathbf{U}_q(\mathfrak{sl}_2)}(\Lambda^{k_1}\bar{\mathbb{Q}}^2 \otimes \dots \otimes \Lambda^{k_d}\bar{\mathbb{Q}}^2) \subset \Lambda^{k_1}\bar{\mathbb{Q}}^2 \otimes \dots \otimes \Lambda^{k_d}\bar{\mathbb{Q}}^2,$$

and  $\Lambda^{k_1}\bar{\mathbb{Q}}^2 \otimes \dots \otimes \Lambda^{k_d}\bar{\mathbb{Q}}^2$  has a **easy** to write down, but **horrible** to work with basis: The elementary tensors  $x_{\vec{g}}$ !

Thus, “identify”  $v \in \mathbf{Inv}_{\mathbf{U}_q(\mathfrak{sl}_2)}(\Lambda^{k_1}\bar{\mathbb{Q}}^2 \otimes \dots \otimes \Lambda^{k_d}\bar{\mathbb{Q}}^2)$  is writing  $v$  in terms of  $x_{\vec{g}}$ .  
Second question: **How** to do it? Recall that the action on tensors is given by

$$\Delta(E_i) = E_i \otimes K_i + 1 \otimes E_i, \quad \Delta(F_i) = F_i \otimes 1 + K_i^{-1} \otimes F_i \quad \text{and} \quad \Delta(K_i) = K_i \otimes K_i.$$

Example:  $\bar{\mathbb{Q}}^2 \otimes \bar{\mathbb{Q}}^2$

Recall that  $\bar{\mathbb{Q}}^2$  has basis  $x_{+1} = (1, 0)$  and  $x_{-1} = (0, 1)$ . Thus,  $\bar{\mathbb{Q}}^2 \otimes \bar{\mathbb{Q}}^2$  has basis  $\{x_{+1+1} = x_{+1} \otimes x_{+1}, x_{+1-1} = x_{+1} \otimes x_{-1}, x_{-1+1} = x_{-1} \otimes x_{+1}, x_{-1-1} = x_{-1} \otimes x_{-1}\}$ .

Test calculation:

$$\begin{aligned} F \cdot x_{+1-1} &= F \cdot x_{+1} \otimes x_{-1} + K^{-1} \cdot x_{+1} \otimes F \cdot x_{-1} \\ &= x_{-1} \otimes x_{-1} \end{aligned}$$

$$\begin{aligned} F \cdot x_{-1+1} &= F \cdot x_{-1} \otimes x_{+1} + K^{-1} \cdot x_{-1} \otimes F \cdot x_{+1} \\ &= q^{+1} x_{-1} \otimes x_{-1} \end{aligned}$$

Claim:  $x_{+1,-1} - q^{-1}x_{-1+1}$  is invariant and spans  $\text{Inv}_{\mathbf{U}_q(\mathfrak{sl}_2)}(\bar{\mathbb{Q}}^2 \otimes \bar{\mathbb{Q}}^2)$ .

How to do this in **general**?

# The diagrammatic calculus helps

## Theorem (Khovanov-Kuperberg 1997)

The decomposition of a  $\mathfrak{sl}_2$ -web  $w \in \mathbf{Mor}(\emptyset, \vec{k})$  in terms of the elementary tensors  $x_{\vec{g}}$  is encoded by the flow lines  $f$  on  $w$  in the following way:

- Each flow  $f$  induces a state string  $\vec{S}_f = (\pm, \dots, \pm)$  at the boundary and has a weight  $\mathbf{wt}(w_f)$ .
- Then the coefficient for  $x_{\vec{S}_f}$  is  $(-q)^{\mathbf{wt}(w_f)}$ .
- Thus,  $w = \sum_f (-q)^{\mathbf{wt}(w_f)} x_{\vec{S}_f}$ .
- (Only  $n = 2!$ ) A basis  $\text{Arc}$  of  $\mathbf{Mor}(\emptyset, \vec{k})$  is given by all arc diagrams.

## Example: $\bar{Q}^2 \otimes \bar{Q}^2$ again

In this case there is exactly one arc  $u$  and it has the two flows

$$\mathbf{wt}(\text{arc with flow } \rightarrow) = 0, \vec{S} = (+1, -1) \quad \text{and} \quad \mathbf{wt}(\text{arc with flow } \leftarrow) = -1, \vec{S} = (-1, +1)$$

**Conclusion:**  $u = x_{+1} \otimes x_{-1} - q^{-1} x_{-1} \otimes x_{+1}$ .

# The negative exponent property

## Example

The diagram shows an equation where a single cup-shaped arc is equal to the sum of four arcs. Each of the four arcs consists of an outer black arc and an inner red arc. The crossings between the black and red arcs are as follows: top-left (black over red), top-right (red over black), bottom-left (red over black), and bottom-right (black over red). Arrows on the red arcs indicate their orientation: top-left (right), top-right (left), bottom-left (right), and bottom-right (left).

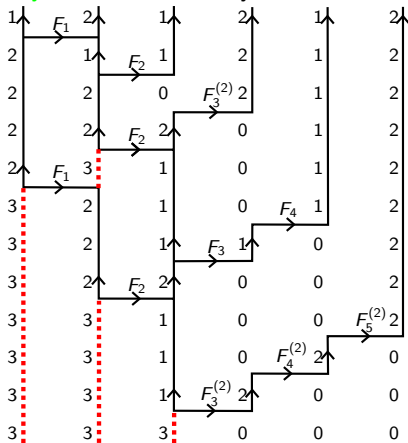

$$\begin{aligned} &= x_{+1} \otimes x_{+1} \otimes x_{-1} \otimes x_{-1} - q^{-1} x_{+1} \otimes x_{-1} \otimes x_{+1} \otimes x_{-1} \\ &\quad - q^{-1} x_{-1} \otimes x_{+1} \otimes x_{-1} \otimes x_{+1} + q^{-2} x_{-1} \otimes x_{-1} \otimes x_{+1} \otimes x_{+1} \end{aligned}$$

Observation: One **leading** term plus a rest with coefficients in  $q^{-1}\mathbb{Z}[q^{-1}]$ ! This is called the **negative exponent property**. In fact, the arc basis is the **dual canonical basis** in the sense of Lusztig.

# $n > 2$ ? Use $q$ -skew Howe!

Roughly:

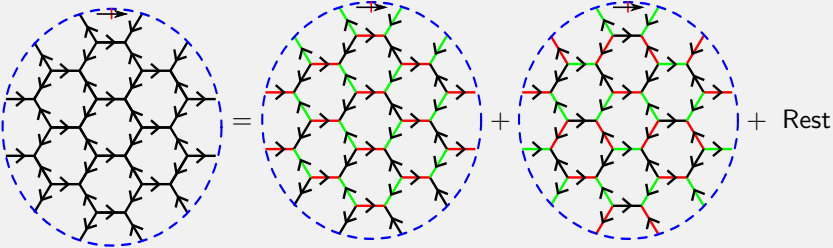

- Express a  $\mathfrak{sl}_n$ -web as a string of  $F$ 's acting on a highest weight vector  $v_{n^\ell}$ .
- The action of the  $F$ 's is given by the splits and merges. Read of the resulting vector inductively.
- There is also a purely combinatorial way to do this!

# Dual canonical $\mathfrak{sl}_n$ -webs? Quantum skew Howe duality!

## Counterexample

$$\begin{aligned} &= x_{+1+1}^2 \otimes x_{+1+1}^1 \otimes x_{00}^2 \otimes x_{00}^1 \otimes x_{-1-1}^2 \otimes x_{-1-1}^1 \\ &+ x_{+1-1}^2 \otimes x_{+1-1}^1 \otimes x_{+1-1}^2 \otimes x_{+1-1}^1 \otimes x_{+1-1}^2 \otimes x_{+1-1}^1 + \text{Rest} \end{aligned}$$

Here Rest has coefficients in  $q^{-1}\mathbb{Z}[q^{-1}]$ .

Note that “most”  $n > 2$ -webs do not have this property and this makes live **very complicated**! But using  $q$ -skew Howe duality one can obtain an **iff-condition** for a web to be dual canonical plus an **algorithm** to compute the dual canonical basis.

# The famous Jones polynomial

Let  $L_D$  be a diagram of an oriented link. Set  $[2] = q + q^{-1}$  and

$n_+$  = number of crossings   $n_-$  = number of crossings 

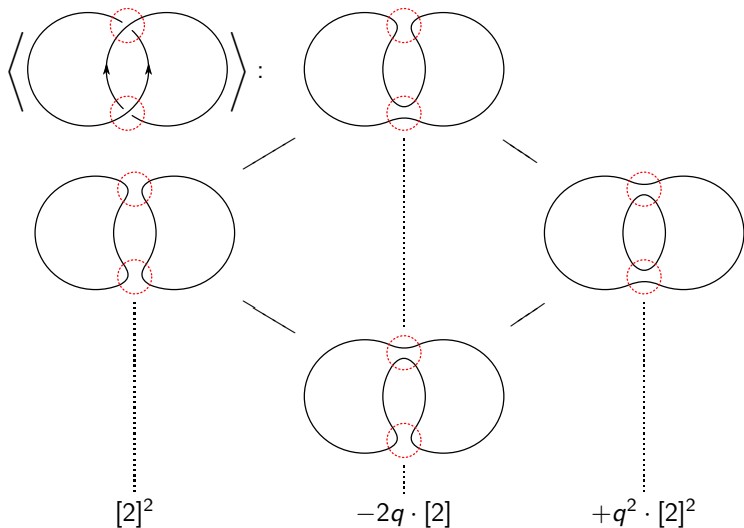

## Definition/Theorem (Jones 1984, Kauffman 1987)

The **bracket polynomial** of the diagram  $L_D$  (without orientations) is a polynomial  $\langle L_D \rangle \in \mathbb{Z}[q, q^{-1}]$  given by the following rules.

- $\langle \emptyset \rangle = 1$  (**normalization**).
- $\langle \diagdown \diagup \rangle = \langle \diagdown \rangle \langle \diagup \rangle - q \langle \text{cup} \rangle$  (**recursion step 1**).
- $\langle \bigcirc \amalg L_D \rangle = [2] \cdot \langle L_D \rangle$  (**recursion step 2**).
- $[2]J(L_D) = (-1)^{n_-} q^{n_+ - 2n_-} \langle L_D \rangle$  (**Re-normalization**).

The polynomial  $J(\cdot) \in \mathbb{Z}[q, q^{-1}]$  is an **invariant** of oriented links.

# Exempli gratia

Thus,  $J(\mathbf{Hopf}) = q^5 + q$ , i.e the Hopf link is **not trivial!**

# “The Jones revolution”

## Definition/Theorem(HOMFLY 1985, PT 1987)

Define a polynomial  $P_n(L_D) \in \mathbb{Z}[q, q^{-1}]$  uniquely determined by the property  $P_n(\bigcirc) = 1$  and the so-called  **$\mathfrak{sl}_n$  skein relations**

$$q^{2n} \cdot P_n(\nearrow \searrow) - q^{-2n} \cdot P_n(\searrow \nearrow) = (q + q^{-1}) \cdot P_n(\uparrow \downarrow).$$

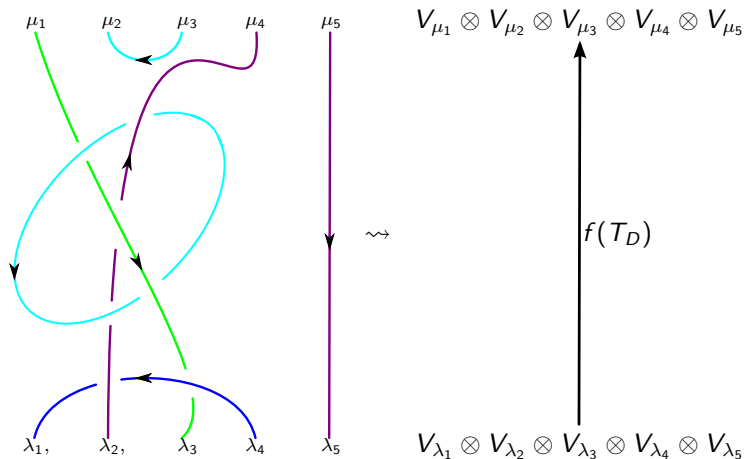

The  **$\mathfrak{sl}_n$ -HOMFLY-PT polynomial** is a **link invariant** and  $P_2(L_D) = J(L_D)$ .

**Shortly** after Jones several authors independently found new knot polynomials. One example is the HOMFLY-PT polynomial. Moreover, researches discovered **connections** to different parts of mathematics and physics. Before the “Jones revolution” there was a **lack** of knot polynomials and after there were **too many**. The questions shifted to:

“Why do they exist? How can we order them?”

# A tangle is an intertwiner

Let  $\mathfrak{g}$  be **any** classical Lie algebra. Denote by  $\lambda_i, \mu_j$  the  $\mathbf{U}_q(\mathfrak{g})$ -representation of highest weight  $V_{\lambda_i}, V_{\mu_j}$ . Let  $T_D$  be a diagram of a,  $\lambda_i, \mu_j$ -colored, oriented tangle.

# Representation theory does the trick!

## Definition (Reshetikhin-Turaev 1990)

Given the set-up from before we define a certain  $\mathbf{U}_q(\mathfrak{g})$ -intertwiner

$$f(T_D): V_{\lambda_1} \otimes \cdots \otimes V_{\lambda_k} \rightarrow V_{\lambda_{k+1}} \otimes \cdots \otimes V_{\lambda_l}.$$

## Theorem (Reshetikhin-Turaev 1990)

The  $\mathbf{U}_q(\mathfrak{g})$ -intertwiner  $f(T_D)$  is an **invariant** of  $T_D$ .

## Corollary (Reshetikhin-Turaev 1990)

In the case of colored, oriented **links**  $L_D$  we have

$$f(L_D): \bar{\mathbb{Q}}(q) \rightarrow \bar{\mathbb{Q}}(q), 1 \mapsto P_{\text{RT}}(L_D) \in \mathbb{Z}[q, q^{-1}],$$

that is each configuration as above gives a **polynomial invariant** of oriented links!

# This is powerful!

## Example

We have the following **list** of examples!

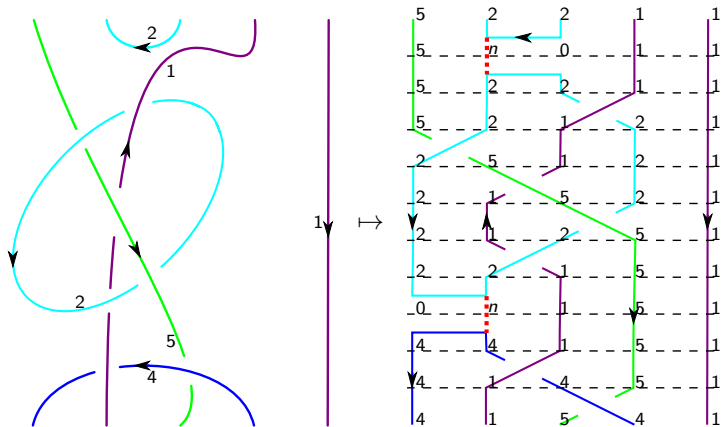

- Let  $\mathfrak{g} = \mathfrak{sl}_2$ . If we **restrict** to the  $\mathbf{U}_q(\mathfrak{sl}_2)$ -vector representation  $\bar{\mathbb{Q}}^2$ , then the Reshetikhin-Turaev polynomial  $P_{\text{RT}}(\cdot)$  is the Jones or  **$\mathfrak{sl}_2$ -polynomial**.
- Let  $\mathfrak{g} = \mathfrak{sl}_2$ . If we allow **any** kind of coloring with  $\mathbf{U}_q(\mathfrak{sl}_2)$ -representations, then  $P_{\text{RT}}(\cdot)$  is the so-called **colored** Jones polynomial.
- Let  $\mathfrak{g} = \mathfrak{sl}_n$ . If we **restrict** to the  $\mathbf{U}_q(\mathfrak{sl}_n)$ -vector representation  $\bar{\mathbb{Q}}^n$ , then the Reshetikhin-Turaev polynomial  $P_{\text{RT}}(\cdot)$  is the  **$\mathfrak{sl}_n$ -polynomial**.
- But the Reshetikhin-Turaev polynomial is much more **generalize** than all of them and **“explains”** them using one concept.

Moral: A lot of link polynomials are **special instances** of **symmetries** of the quantum groups  $\mathbf{U}_q(\mathfrak{g})!$

Question: Can we do this more explicit for  $\mathfrak{g} = \mathfrak{sl}_n$ ?

# “Straightening” again

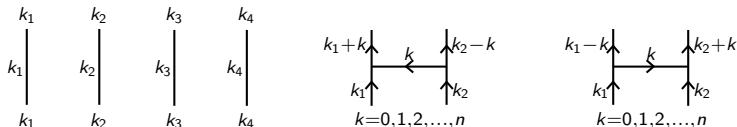

Consider a diagram of an oriented tangle. Its components can be colored with colors  $k \in \{0, \dots, n\}$ . These colors correspond to the fundamental  $\mathbf{U}_q(\mathfrak{sl}_n)$ -representations  $\Lambda^k \bar{\mathbb{Q}}^n$ . Straightening it into a Morse position.

# Tangles to $\mathfrak{sl}_n$ -webs

We can define as before the category  $\mathbf{Sp}(\mathbf{U}_q(\mathfrak{sl}_n))$  consisting of 1-cells as

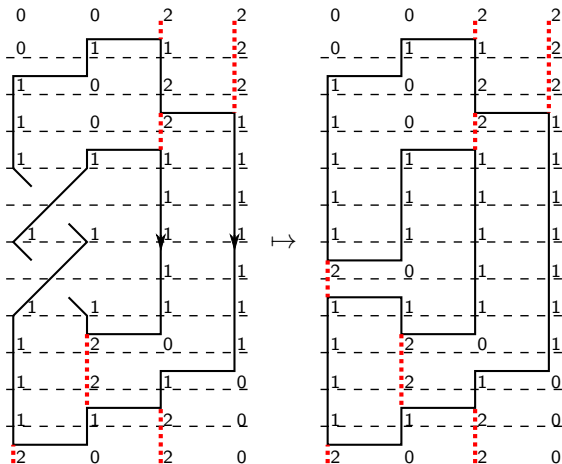

Let  $b \leq a$ . Define an  $\mathbf{U}_q(\mathfrak{sl}_n)$ -intertwiner  $\Lambda^a \bar{\mathbb{Q}}^n \otimes \Lambda^b \bar{\mathbb{Q}}^n \rightarrow \Lambda^b \bar{\mathbb{Q}}^n \otimes \Lambda^a \bar{\mathbb{Q}}^n$  as follows.

$$\begin{array}{c} \nearrow \\ a \end{array} \begin{array}{c} \nearrow \\ b \end{array} = \sum_{k=0}^b (-1)^{k+(a+1)b} q^{-b+k} \begin{array}{c} b \qquad a \\ \uparrow \qquad \uparrow \\ a+k \qquad b-k \\ \leftarrow \qquad \rightarrow \\ \uparrow \qquad \uparrow \\ a \qquad b \end{array}$$

“Morally” (up to some signs, shifts, re-orientations) the same for  $a < b$  and  $\nearrow \searrow$ .

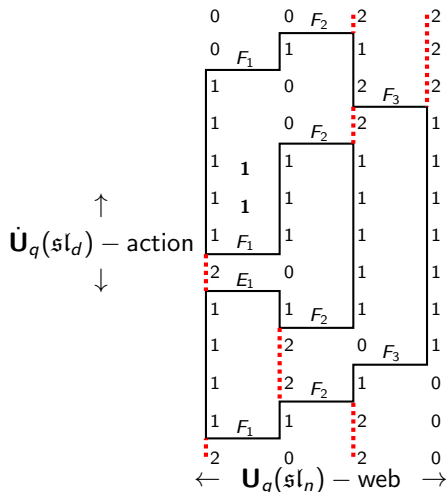

# Exempli gratia: Hopf link for $\mathfrak{sl}_2$

$f_{10}(\mathbf{Hopf}) : \Lambda^2 \bar{\mathbb{Q}}^2 \otimes \bar{\mathbb{Q}} \otimes \Lambda^2 \bar{\mathbb{Q}}^2 \otimes \bar{\mathbb{Q}} \rightarrow \bar{\mathbb{Q}} \otimes \bar{\mathbb{Q}} \otimes \Lambda^2 \bar{\mathbb{Q}}^2 \otimes \Lambda^2 \bar{\mathbb{Q}}^2$  is an **intertwiner** in  $\mathbf{Sp}(\mathbf{U}_q(\mathfrak{sl}_n))$ . In the end we get the **same polynomial** as before (up to a shift).

Conclusion: Works **fine** for  $n = 2$ . What about  $n > 2$ ?

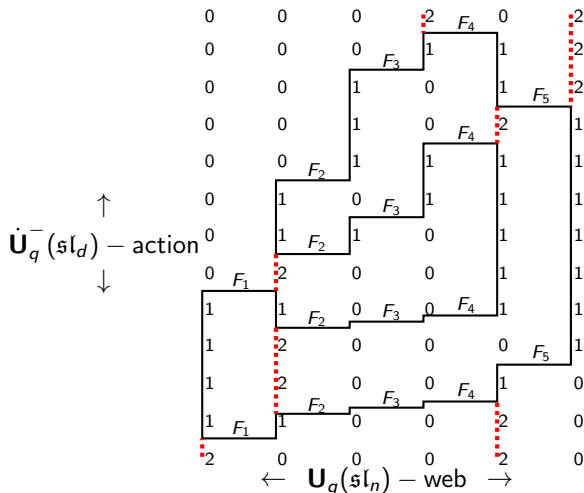

# Quantum skew Howe duality helps

Recall that we have an  $\dot{U}_q(\mathfrak{sl}_d)$ -action on  $\mathbf{Sp}(U_q(\mathfrak{sl}_n))^{(d)}$ . In the example above

$$f_{10}(\mathbf{Hopf}) = F_2 F_1 F_3 F_2 F_1 E_1 F_2 F_3 F_2 F_1 F_2^{(2)} v_{2200}.$$

The lower part  $\dot{\mathbf{U}}_q^-(\mathfrak{sl}_d)$  suffices!

A crucial observation: We need **only**  $F$ 's!

$$f_{10}(\mathbf{Hopf}) = F_4^{(2)} F_4 F_3 F_5 F_4 F_2 F_3 F_2 F_1 F_4 F_3 F_2 F_5 F_4 F_3 F_2 F_1 F_4^{(2)} F_3^{(2)} F_2^{(2)} v_{220000}.$$

# The $\mathfrak{sl}_n$ -polynomials using $\mathfrak{sl}_d$ -symmetries

Let us **summarize** the connection between (colored)  $\mathfrak{sl}_n$ -polynomials and the  $\dot{\mathbf{U}}_q(\mathfrak{sl}_d)$ - $\mathbf{U}_q(\mathfrak{sl}_n)$ -skew Howe duality.

- Reshetikhin-Turaev: The  $\mathfrak{sl}_n$ -polynomials  $P_n(\cdot)$  are  $\mathbf{U}_q(\mathfrak{sl}_n)$ -intertwiner.
- $\mathbf{U}_q(\mathfrak{sl}_n)$ -intertwiner are vectors in hom's between  $\dot{\mathbf{U}}_q(\mathfrak{sl}_d)$ -weight spaces.
- Only  $F$ 's: The space of invariant  $\mathbf{U}_q(\mathfrak{sl}_n)$ -tensors is a  $\dot{\mathbf{U}}_q(\mathfrak{sl}_d)$ -representation of some highest weight  $v_h$  and  $\dot{\mathbf{U}}_q^-(\mathfrak{sl}_d)$  suffices.
- Conclusion: The (colored)  $\mathfrak{sl}_n$ -polynomials  $P_n(\cdot)$  are instances of highest  $\dot{\mathbf{U}}_q(\mathfrak{sl}_d)$ -weight representation theory!
- If  $L_D$  is a link diagram, then  $P_n(L_D)$  is obtained by jumping via  $F$ 's from a highest  $\dot{\mathbf{U}}_q(\mathfrak{sl}_d)$ -weight  $v_h$  to a lowest  $\dot{\mathbf{U}}_q(\mathfrak{sl}_d)$ -weight  $v_l$ !

There is still **much** to do...

Thanks for your attention!
