

**What is...mathematical biology?**

---

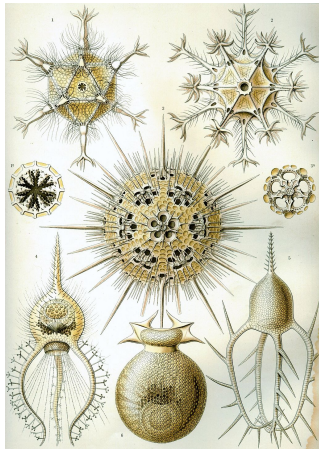

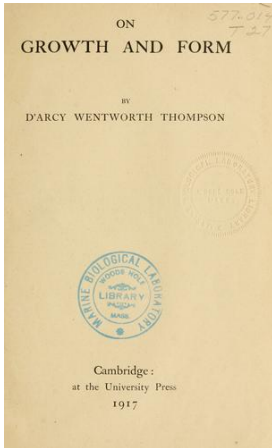

Or: Subfields of mathematics 14

# Rabbit counting

- ▶ Early mathematical biology (MB) Rabbit counting
- ▶ This is a prototypical example of a model
- ▶ Fibonacci was way ahead of their time

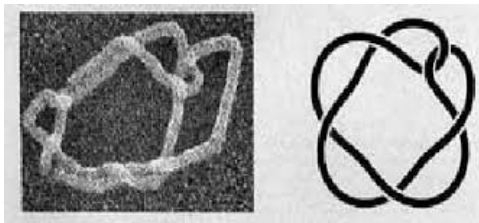

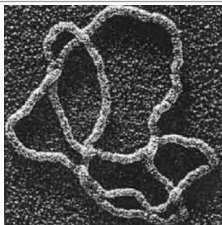

# The beginnings

- ▶ **On Growth and Form (1917)** is often regarded as the first instance of MB
- ▶ **Example** It is argued that the weight of an animal increase with the cube of its length
- ▶ **Catch** Thompson (the author) rejected natural selection

# Life is hard

---

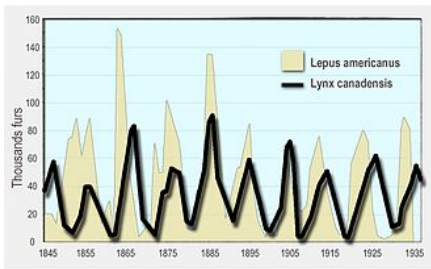

- 
- ▶ Complexity of life  $\Rightarrow$  MB uses most fields of mathematics
  - ▶ One often has surprising connections
  - ▶ Example The way how DNA forms knots is determines many of its properties

## Enter, the theorem

The Lotka–Volterra equation is (t = time):

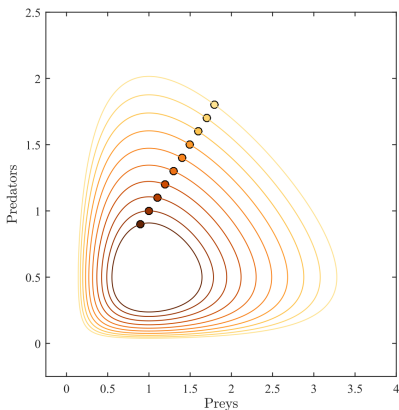

$$dx/dt = \alpha x - \beta xy \text{ and } dy/dt = -\gamma y + \delta xy \text{ with } \alpha, \beta, \gamma, \delta \in \mathbb{R}_{>0}$$

This models the prey-predator dynamics

- ▶  $x = \#$  'rabbits',  $y = \#$  'foxes',  $\alpha, \delta =$  growth rate,  $\beta, \gamma =$  death rate
- ▶ Nowadays differential equations are use everywhere to model the world
- ▶ MB answers similar questions!

# Population dynamics

- ▶ Above  $\alpha = 2/3$ ,  $\beta = 4/3$ ,  $\gamma = \delta = 1$  and different starting values
- ▶ Note the fixed point (= equilibrium) at (1, 0.5)
- ▶ Upshot We can use mathematics to explain the behavior of population growth

**Thank you for your attention!**

---

I hope that was of some help.
