

wKLRW algebras and crystals

Or: From path to strings

Daniel Tubbenhauer

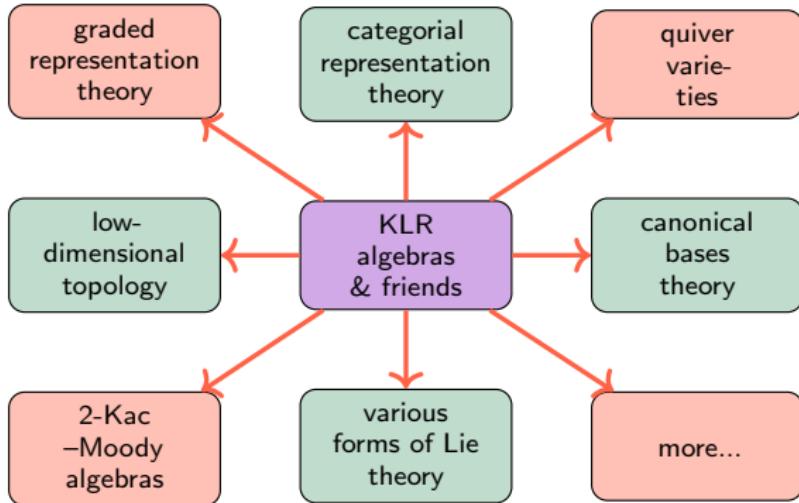

$$C_3 : \quad \begin{array}{c} \bullet \rightarrow \bullet \leftarrow \bullet \\ 1 \qquad \qquad \qquad 2 \qquad \qquad \qquad 3 \end{array}$$

Joint with Andrew Mathas

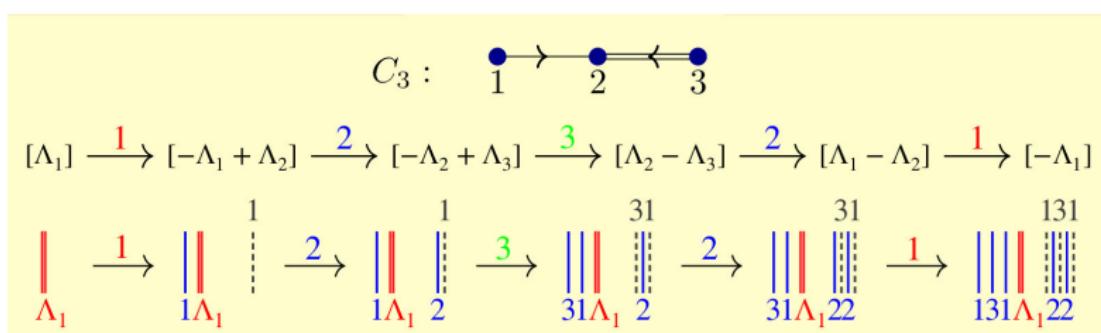

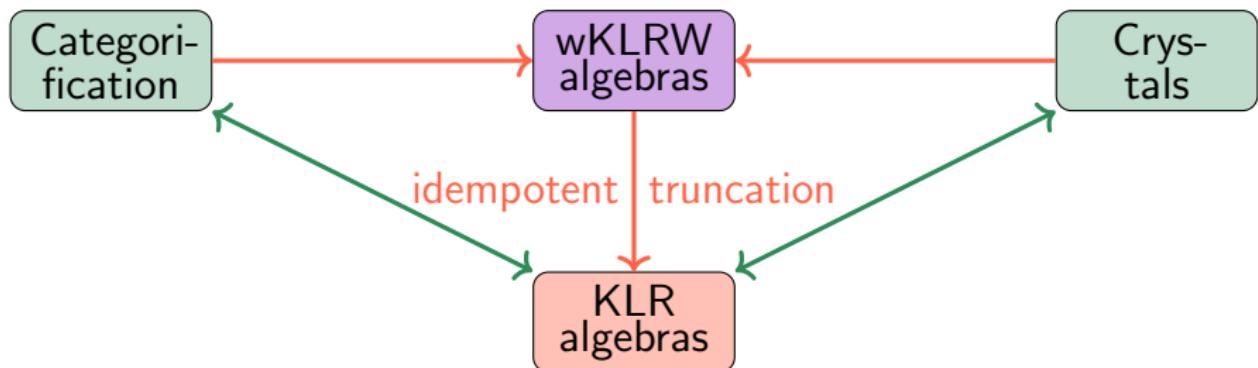

September 2022

What? Why? How?

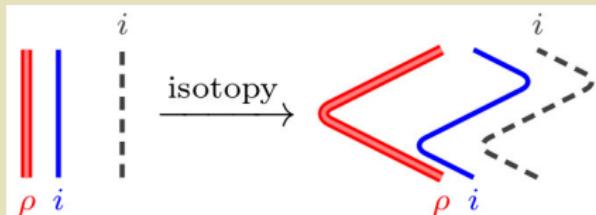

- ▶ **Khovanov–Lauda–Rouquier ~2008 + many others** (including many people here) KLR algebras are at the heart of categorical representation theory
- ▶ **Problem** These are actually really complicated!
- ▶ **Goal** Try to find nice (“cellular”) bases for them

What? Why? How?

Use a richer combinatorics which is somewhat easier although more sophisticated

1) The diagram combinatorics

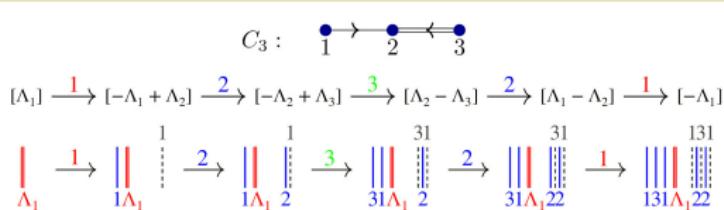

2) Sandwich cellularity

cellular: $c_{T,1,B}^\lambda \longleftrightarrow \begin{array}{c} T \\ B \end{array}$ $\leftarrow \mathcal{H}_\lambda \cong \mathbb{K}$, affine cellular: $c_{T,m,B}^\lambda \longleftrightarrow \begin{array}{c} T \\ m \\ B \end{array}$ \leftarrow commutative \mathcal{H}_λ

sandwich cellular: $c_{T,m,B}^\lambda \longleftrightarrow \begin{array}{c} T \\ m \\ B \end{array}$ \leftarrow general \mathcal{H}_λ ,

3) Bases and crystals

String diagrams – the baby case

Connect eight points at the bottom with eight points at the top:

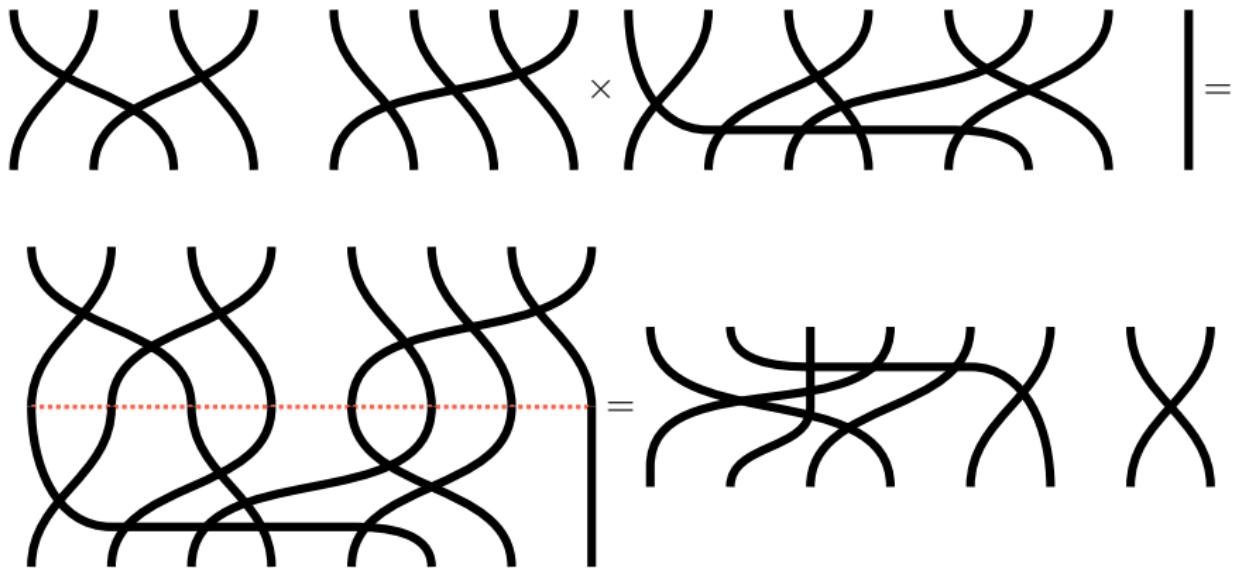

or

We just invented the symmetric group S_8 on $\{1, \dots, 8\}$

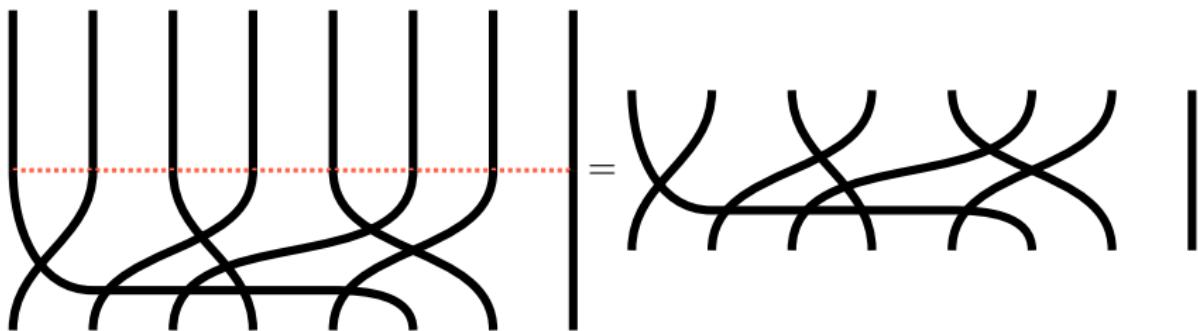

String diagrams – the baby case

My multiplication rule for gh is “stack g on top of h ”

String diagrams – the baby case

- We clearly have $g(hf) = (gh)f$
- There is a do nothing operation $1g = g = g1$

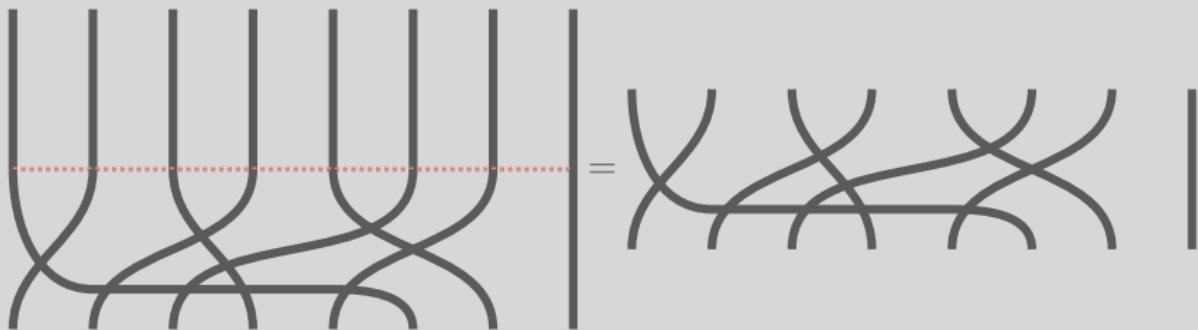

- Generators–relations (the Reidemeister moves)

String diagrams –

The bait

- We clearly have relations, properties, etc. become visually clear
- There is a do nothing operation $1g = g = g1$

- Generators-relations (the Reidemeister moves)

String diagrams –

The bait

- We clearly have relations, properties, etc. become visually clear
- There is a do nothing operation $1g = g = g1$

The catch

Diagram algebras are usually “not really” using any planar geometry

For example, the diagrams for symmetric groups
are just algebra written differently

- Generators–relations (the Reidemeister moves)

gens :

rels : = ,

=

String diagrams –

The bait

- We clearly have relations, properties, etc. become visually clear
- There is a do nothing operation $1g = g = g1$

The catch

Diagram algebras are usually “not really” using any planar geometry

For example, the diagrams for symmetric groups
are just algebra written differently

- Generating functions (Hilbert series)

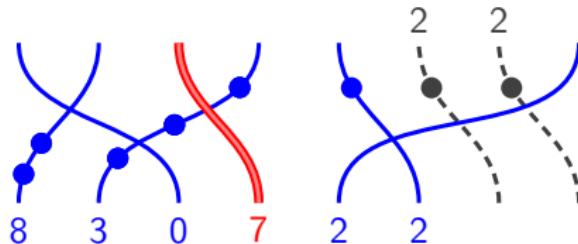

Idea (Webster ~2012)

Define a diagram algebra that uses the distance in \mathbb{R}^2

The result is called weighted KLRW (wKLRW) algebra

These are “planar-geometrically symmetric group diagram algebras”

Weighted string diagrams

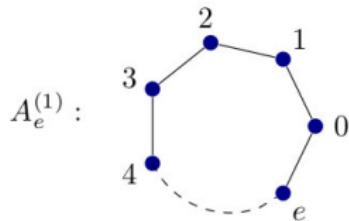

- Strings come in three types, solid, ghost and red

solid :  , ghost :  , red :  ,

- Strings are labeled, and solid and ghost strings can carry dots
- Red strings anchor the diagram (red strings \rightsquigarrow level)
- Otherwise no difference to symmetric group diagrams

Weighted string diagrams

$$A_{\mathbb{Z}} : \cdots -3 -2 -1 0 1 2 3 \cdots$$

Examples of quivers Γ

An additional orientation fixes signs

$$C_{\mathbb{Z}_{\geq 0}} : 0 \rightarrow 1 \rightarrow 2 \rightarrow 3 \rightarrow 4 \rightarrow 5 \rightarrow 6 \cdots$$

$$C_e^{(1)} : 0 \rightarrow 1 \rightarrow 2 \rightarrow 3 \rightarrow \cdots \rightarrow e-2 \rightarrow e-1 \leftarrow e$$

- The strings are labeled by $i \in I$ from a fixed quiver $\Gamma = (I, E)$
- The relations (that I am not going to show you ;-)) depend on $e \in E$, e.g.:

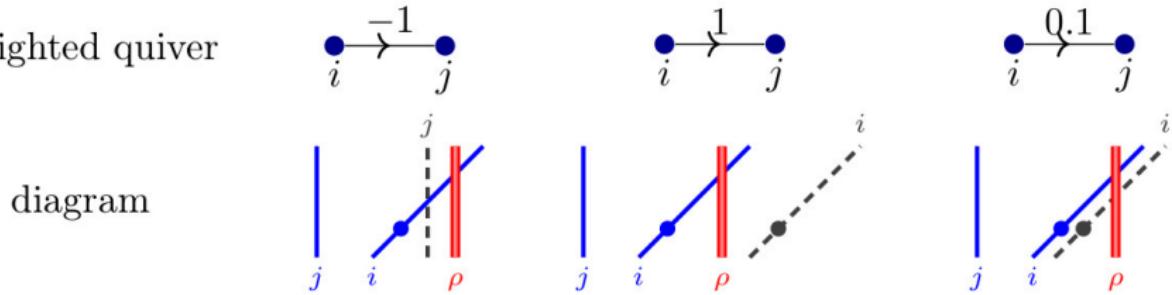

“Reidemeister II
with error term”

$$\begin{array}{c} \text{“Reidemeister II} \\ \text{with error term”} \end{array} : \quad \begin{array}{c} \text{Diagram showing two configurations of strands } i \text{ and } j \text{ meeting at a vertex.} \\ \text{Left: Two strands } i \text{ and } j \text{ cross.} \\ \text{Middle: The strands pass through each other.} \\ \text{Right: The strands pass through each other again, with a sign change.} \end{array} = \quad \begin{array}{c} \text{Diagram showing two configurations of strands } i \text{ and } j \text{ meeting at a vertex.} \\ \text{Left: Two strands } i \text{ and } j \text{ cross.} \\ \text{Middle: The strands pass through each other.} \\ \text{Right: The strands pass through each other again, with a sign change.} \end{array} \quad \text{if } i \rightarrow j$$

$$X = (-2\sqrt{3}, -\sqrt{2}, 0.5, \pi, 5) \rightsquigarrow$$

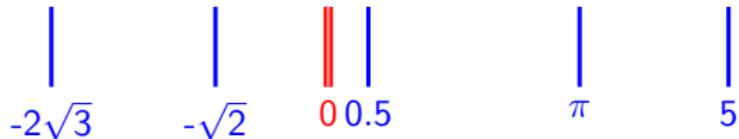

Weighted quiver

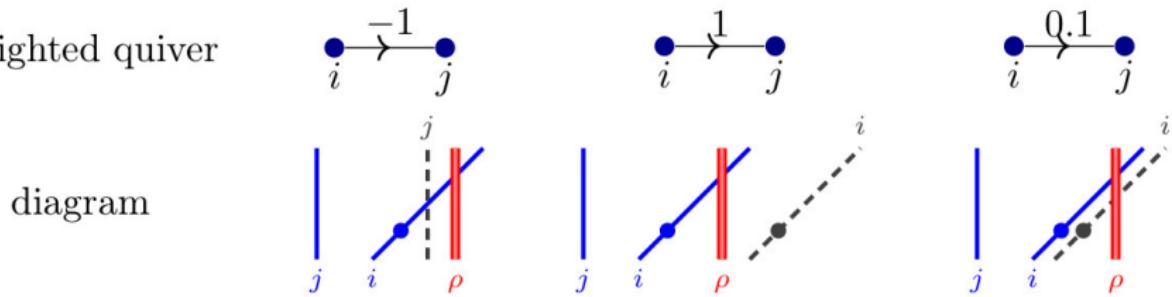

- ▶ Choose endpoints $x = (x_1, \dots, x_n) \in \mathbb{R}^n$, $\rho \in \mathbb{R}^\ell$ for the solid and red strings
- ▶ Choose a weighting $\sigma: E \rightarrow \mathbb{R}_{\neq 0}$ of the underlying graph $\Gamma = (I, E)$
- ▶ The wKLRW algebra crucially depends on these choices of endpoints! This is very different from “usual diagram algebras”

Weighted string diagrams

$$X = (-2\sqrt{3}, -\sqrt{2}, 0.5, \pi, 5) \leftrightarrow$$

Weighted quiver

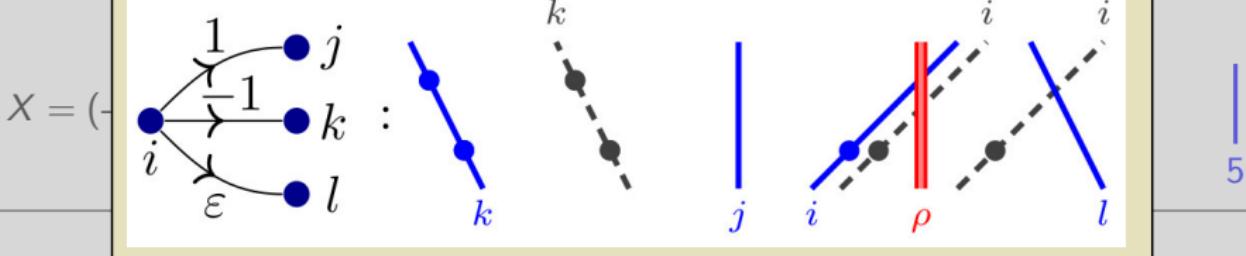

Weighting = ghost shifts

For $\epsilon: i \rightarrow j, \sigma_\epsilon > 0$, all solid i -strings get a ghost shifted $|\sigma_\epsilon|$ units and mimicking it
For $\epsilon: i \rightarrow j, \sigma_\epsilon < 0$, all solid j -strings get a ghost shifted $|\sigma_\epsilon|$ units and mimicking it

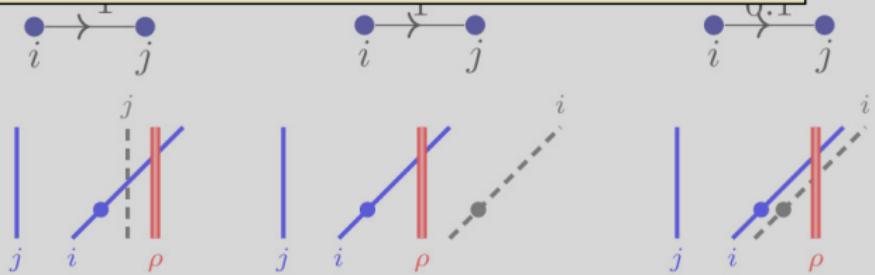

- The wKLR This “asymmetric” definition, always shifting rightwards points! This is very different makes life a bit more convenient but is not essential

Weighted string diagrams

Weighted quiver

diagram

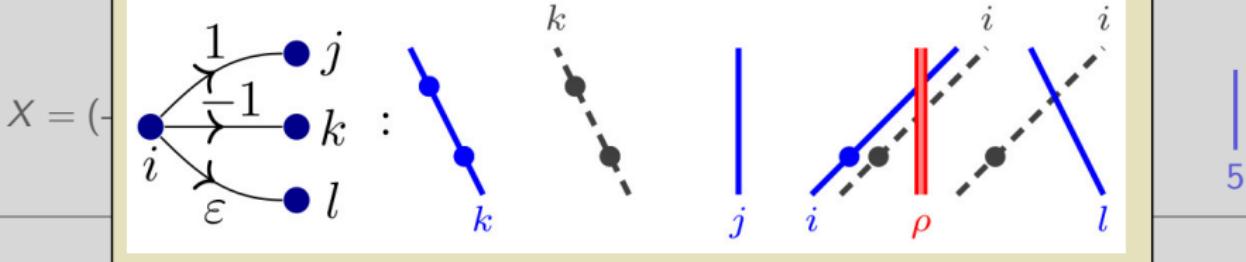

Weighting = ghost shifts

For $\epsilon: i \rightarrow j, \sigma_\epsilon > 0$, all solid i -strings get a ghost shifted $|\sigma_\epsilon|$ units and mimicking it
 For $\epsilon: i \rightarrow j, \sigma_\epsilon < 0$, all solid j -strings get a ghost shifted $|\sigma_\epsilon|$ units and mimicking it

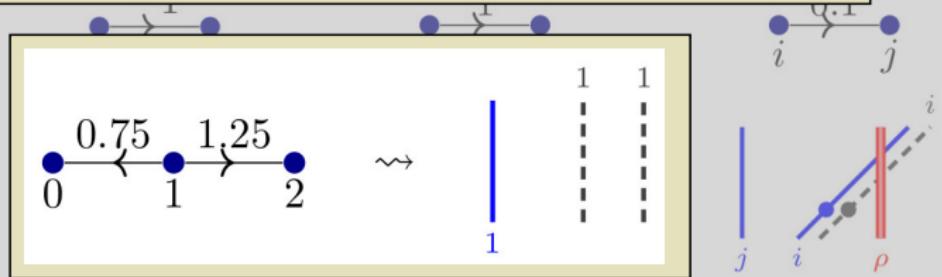

- The wKLRW algebra crucially depends on these choices of endpoints! This is very different from “usual diagram algebras”

Weighted string diagrams

Weighted
diagram

For “good choices” of X :	
Semisimple	Huge ghost shifts
KLR	Tiny ghost shifts
Quiver Schur	Some specific “cluster” spacing
Diagrammatic Cherednik	Ghost shifts 1
Unnamed algebras	The rest

- ▶ Choose endpoints $x = (x_1, \dots, x_n) \in \mathbb{R}^n$, $\rho \in \mathbb{R}^\ell$ for the solid and red strings
- ▶ Choose a weighting $\sigma: E \rightarrow \mathbb{R}_{\neq 0}$ of the underlying graph $\Gamma = (I, E)$
- ▶ The wKLRW algebra crucially depends on these choices of endpoints! This is very different from “usual diagram algebras”

Sandwiches

Definition 2A.3. A *sandwich cell datum* for \mathcal{A} is a quadruple $(\mathcal{P}, (\mathcal{T}, \mathcal{B}), (\mathcal{H}_\lambda, B_\lambda), C)$, where:

- $\mathcal{P} = (\mathcal{P}, <_{\mathcal{P}})$ is a poset (the *middle poset* with *sandwich order* $<_{\mathcal{P}}$),
- $\mathcal{T} = \bigcup_{\lambda \in \mathcal{P}} \mathcal{T}(\lambda)$ and $\mathcal{B} = \bigcup_{\lambda \in \mathcal{P}} \mathcal{B}(\lambda)$ are collections of finite sets (the *top/bottom sets*),
- For $\lambda \in \mathcal{P}$ we have algebras \mathcal{H}_λ (the *sandwiched algebras*) and bases B_λ of \mathcal{H}_λ ,
- $C: \coprod_{\lambda \in \mathcal{P}} \mathcal{T}(\lambda) \times B_\lambda \times \mathcal{B}(\lambda) \rightarrow \mathcal{A}; (T, m, B) \mapsto c_{T,m,B}^\lambda$ is an injective map,

such that:

(AC₁) The set $B_{\mathcal{A}} = \{c_{T,m,B}^\lambda \mid \lambda \in \mathcal{P}, T \in \mathcal{T}(\lambda), B \in \mathcal{B}(\lambda), m \in B_\lambda\}$ is a basis of \mathcal{A} . (We call $B_{\mathcal{A}}$ a *sandwich cellular basis*.)

(AC₂) For all $x \in \mathcal{A}$ there exist scalars $r_{TU}^x \in \mathbb{K}$ that do not depend on B or on m , such that

$$(2A.4) \quad xc_{T,m,B}^\lambda \equiv \sum_{U \in \mathcal{T}(\lambda) n \in B_\lambda} r_{TU}^x c_{U,n,B}^\lambda \pmod{\mathcal{A}^{>_{\mathcal{P}} \lambda}}.$$

Similarly for right multiplication by x .

(AC₃) There exists a free \mathcal{A} - \mathcal{H}_λ -bimodule $\Delta(\lambda)$, a free \mathcal{H}_λ - \mathcal{A} -bimodule $\nabla(\lambda)$, and an \mathcal{A} -bimodule isomorphism

$$(2A.5) \quad \mathcal{A}_\lambda = \mathcal{A}^{\geq_{\mathcal{P}} \lambda} / \mathcal{A}^{>_{\mathcal{P}} \lambda} \cong \Delta(\lambda) \otimes_{\mathcal{H}_\lambda} \nabla(\lambda).$$

We call \mathcal{A}_λ the *cell algebra*, and $\Delta(\lambda)$ and $\nabla(\lambda)$ left and right *cell modules*.

The algebra \mathcal{A} is a *sandwich cellular algebra* if it has a sandwich cell datum.

The

$$\mathbb{K}\mathcal{L}_\lambda \cong \mathbb{K}\mathcal{T}(\lambda) \otimes_{\mathbb{K}} \mathcal{H}_\lambda \rightsquigarrow \begin{array}{c} T \\ m \\ B \end{array}, \quad \mathbb{K}\mathcal{R}_\lambda \cong \mathcal{H}_\lambda \otimes_{\mathbb{K}} \mathbb{K}\mathcal{B}(\lambda) \rightsquigarrow \begin{array}{c} T \\ m \\ B \end{array},$$

$$\mathcal{J}_\lambda \cong \mathbb{K}\mathcal{T}(\lambda) \otimes_{\mathbb{K}} \mathcal{H}_\lambda \otimes_{\mathbb{K}} \mathbb{K}\mathcal{B}(\lambda) \rightsquigarrow \begin{array}{c} T \\ m \\ B \end{array}, \quad \mathbb{K}\mathcal{H}_\lambda \cong \mathcal{H}_\lambda \rightsquigarrow \begin{array}{c} T \\ m \\ B \end{array}.$$

Example

De

All algebras are sandwich cellular with $\mathcal{P} = \{\bullet\}$ and $\mathcal{H}_\bullet = \mathcal{A}$

We get the fantastic tautology:

$$\left\{ \begin{array}{c} \text{simples of} \\ \mathcal{A} \end{array} \right\} = \left\{ \begin{array}{c} \text{simples asso-} \\ \text{ciated to } \bullet \end{array} \right\} \xleftrightarrow{\text{one-to-one}} \left\{ \begin{array}{c} \text{simples of} \\ \mathcal{H}_\bullet \end{array} \right\} = \left\{ \begin{array}{c} \text{simples of} \\ \mathcal{A} \end{array} \right\}$$

The point is to find a good sandwich datum!

Definition 2A.3. A **Many monoid algebras with the monoid basis** $(\mathcal{H}_\lambda, B_\lambda), C)$, where:

- $\mathcal{P} = (\mathcal{P}, <_{\mathcal{P}})$ is a poset (the *middle poset* with *sandwich order* $<_{\mathcal{P}}$),

Example

KLR algebras of many types as we will see

Let us sandwich wKLRW diagrams!

- Cyclotomic (fin dim) quotients \Leftrightarrow bounded regions:

not unsteady:

- Sandwich cellular bases \Leftrightarrow minimal regions (I will elaborate momentarily):

(1^3) :

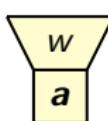

0
1

1
2

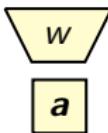

- More properties I won't explain today due to time restrictions...

Let us sandwich wKLRW diagrams!

- wKLRW algebras have standard bases , with the picture:

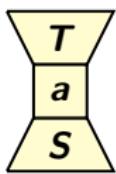

with

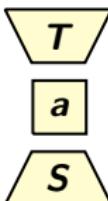

is a permutation diagram,

is an idempotent with dots.

- wKLRW algebras often have sandwich cellular bases , with the picture:

with

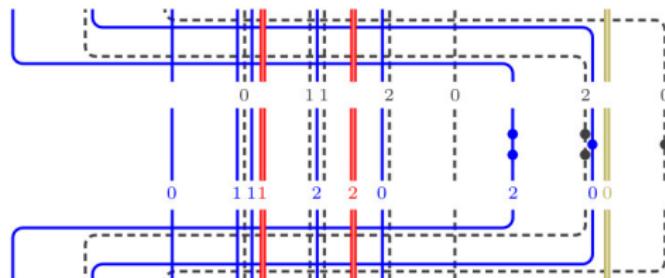

is a permutation diagram,

is an idempotent with dots,

is a permutation diagram.

Let us sandwich

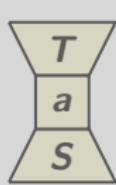

- ▶ wKLRW algebras

► Standard bases work regardless of the quiver but have no other property despite being a basis

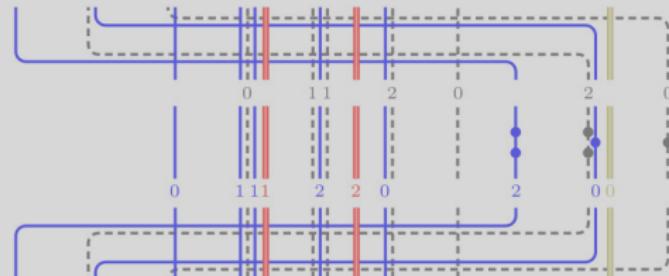

► Sandwich cellular bases depend on the quiver and give a classification of simple modules

► What is sandwiched are
(quotients of) polynomial algebras

- ▶ wKLRW algebras often have sandwich cellular bases , with the picture:

with  is a permutation diagram,
 is an idempotent with dots,
 is a permutation diagram.

Or: From path to strings

Let us sandwich

- ▶ wKLRW algebras

► Standard bases work regardless of the quiver but have no other property despite being a basis

► Sandwich cellular bases depend on the quiver and give a classification of simple modules

► What is sandwiched are
(quotients of) polynomial algebras

am,
dots.

► The overall strategy to construct such bases
is the same for all types (but the details differ)

and for the infinite dimensional and the cyclotomic case the construction is also the same

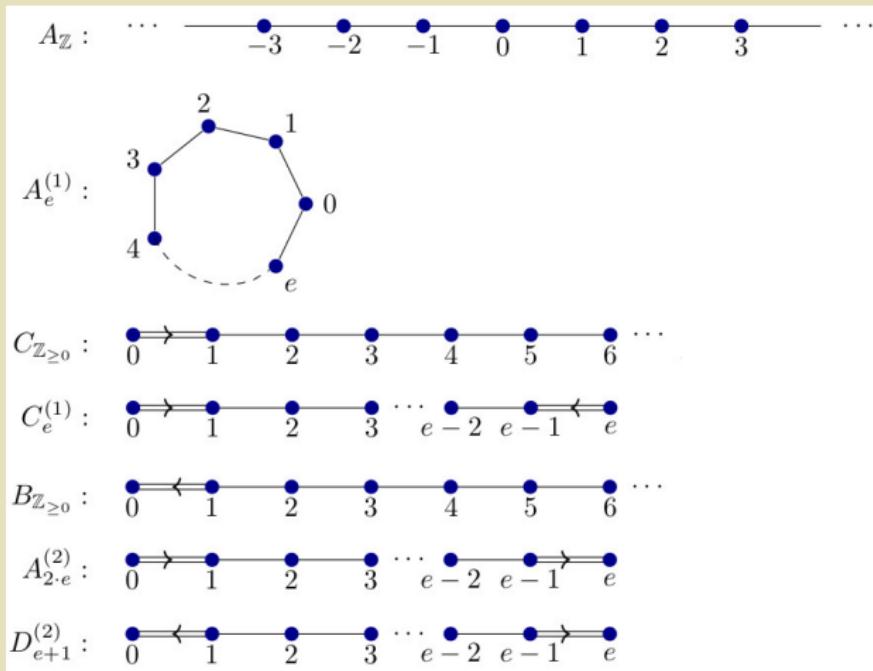

► We know that the cellular bases work in types $A_{\mathbb{Z}}$, $A_e^{(1)}$, $B_{\mathbb{N}}$, $C_e^{(1)}$, $A_{2e}^{(2)}$, $D_{e+1}^{(2)}$
other, in particular finite, types are work in progress

► The combinatorics is inspired by, but different from, constructions of
Bowman ~2017, Ariki–Park ~2012/2013, Ariki–Park–Speyer ~2017

Summary of the before

We know cellularity in these cases (for inf dim and cyclotomic quotients):

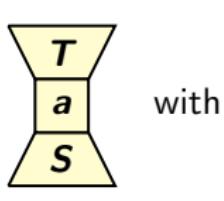

95% theorem This list can be extended to contain all finite types, $E_6^{(2)}$, $F_4^{(1)}$, $G_2^{(1)}$

Open Compare our inf dim case for finite types to **Kleshchev–Loubert–Miemietz** ~2013

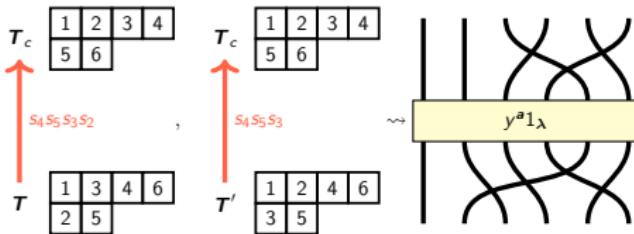

Let us sandwich wKLRW diagrams!

$$C_e^{(1)} : \quad 0 \xrightarrow{\hspace{1cm}} 1 \xrightarrow{\hspace{1cm}} 2 \xrightarrow{\hspace{1cm}} 3 \cdots e-2 \xrightarrow{\hspace{1cm}} e-1 \xleftarrow{\hspace{1cm}} e$$

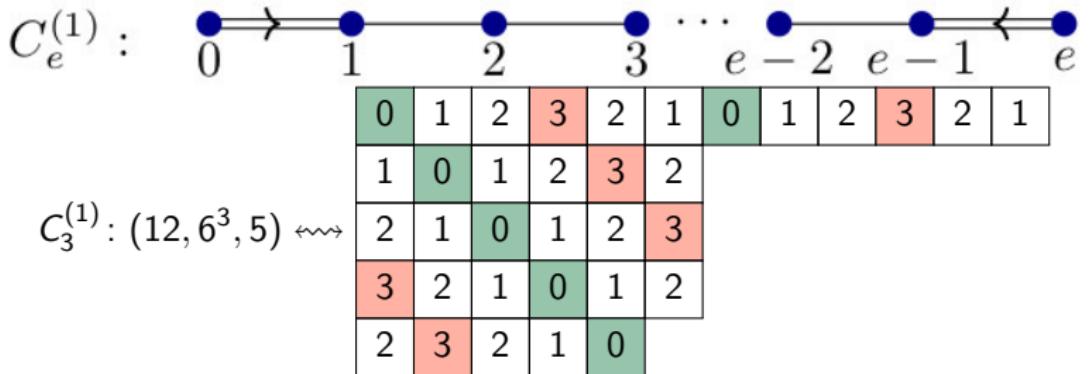

is a permutation diagram,
with is an idempotent with dots,
 is a permutation diagram.

- The definition of the permutation follows the usual strategy in this context:

- The main meat Let me focus on the middle $y^a 1_\lambda$

Let us sandwich wKLRW diagrams!

- ▶ Assume the tableaux combinatorics is given (a better statement later!)
- ▶ Place strings inductively as far to the right as possible (this is the order!)
- ▶ 1_λ is minimal with respect to placing the strings to the right
- ▶ 1_λ stays minimal when dots are put on certain strands \rightsquigarrow get $y^\alpha 1_\lambda$
- ▶ Done!

Let us sandwich wKLRW diagrams!

Lets ignore the dots for today – I bothered you with too much combinatorics anyway ;-)
 But they come directly from the Reidemeister II relations, e.g.

$$\begin{array}{c} \text{---} \\ i \\ | \\ \bullet \\ j \end{array} = \begin{array}{c} \text{---} \\ i \\ | \\ \text{---} \\ j \end{array} + \begin{array}{c} \text{---} \\ i \\ | \\ \bullet \\ j \end{array}, \quad \begin{array}{c} \text{---} \\ j \\ | \\ \bullet \\ i \end{array} = \begin{array}{c} \text{---} \\ j \\ | \\ \bullet \\ i \end{array} - \begin{array}{c} \text{---} \\ j \\ | \\ \text{---} \\ i \end{array} \quad \text{for either of } \begin{cases} i = 0, j = 1, \\ i = e, j = e - 1, \end{cases}$$

This gives us the notion of the rightmost **parking slot** where strings are **blocked**

In other words: **Stare at Reidemeister II !**

- ▶ Place strings inductively as far to the right as possible (this is the order!)
- ▶ 1_λ is **minimal** with respect to placing the strings to the right
- ▶ 1_λ **stays minimal** when dots are put on certain strands \rightsquigarrow get $y^a 1_\lambda$
- ▶ **Done!**

Let us sandwich wKLRW diagrams!

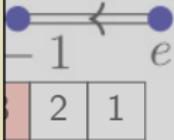

$C_e^{(1)} :$

Example for the middles $y^a \mathbf{1}_\lambda$

$$y_{(1^5)} \mathbf{1}_{(1^5)} = \begin{array}{c} || \\ 00 \end{array}$$

$$\begin{array}{c} 0 \\ | \\ 3 \quad 1 \\ | \end{array}$$

$$\begin{array}{c} 3 \quad 1 \\ | \\ 2 \quad 2 \\ | \end{array}$$

$C_3^{(1)} : (12$

$$y_{(5)} \mathbf{1}_{(5)} = \begin{array}{c} || \\ 00 \end{array}$$

$$\begin{array}{c} 0 \\ | \\ 3 \quad 1 \\ | \end{array}$$

$$\begin{array}{c} 3 \quad 1 \\ | \\ 2 \quad 2 \\ | \end{array}$$

► Assume the t

ment later!)

► Place strings

s is the order!)

► $\mathbf{1}_\lambda$ is minima

ight

► $\mathbf{1}_\lambda$ stays min

get $y^a \mathbf{1}_\lambda$

► Done!

$$y_{(2,1^3)} \mathbf{1}_{(2,1^3)} = \begin{array}{c} || \\ 00 \end{array}$$

$$\begin{array}{c} 0 \\ | \\ 3 \quad 11 \\ | \end{array}$$

$$\begin{array}{c} 3 \quad 11 \\ | \\ 2 \end{array}$$

$$y_{(4,1)} \mathbf{1}_{(4,1)} = \begin{array}{c} || \\ 00 \end{array}$$

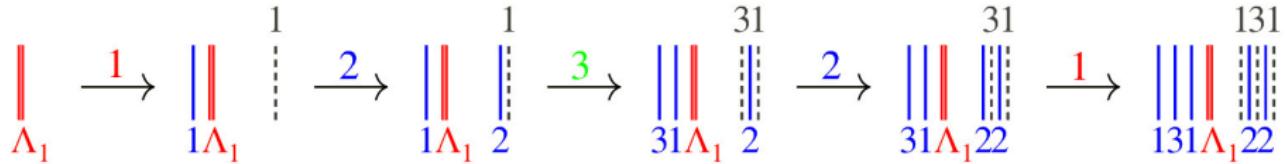

$$\begin{array}{c} 0 \\ | \\ 13 \quad 1 \\ | \end{array}$$

$$\begin{array}{c} 13 \quad 1 \\ | \\ 2 \end{array}$$

The (conjectural) picture for a lot of types

$$C_3 : \quad \begin{array}{c} \bullet \rightarrow \bullet \leftarrow \bullet \\ 1 \qquad \qquad \qquad 2 \qquad \qquad \qquad 3 \end{array}$$

$$[\Lambda_1] \xrightarrow{\textcolor{red}{1}} [-\Lambda_1 + \Lambda_2] \xrightarrow{\textcolor{blue}{2}} [-\Lambda_2 + \Lambda_3] \xrightarrow{\textcolor{green}{3}} [\Lambda_2 - \Lambda_3] \xrightarrow{\textcolor{blue}{2}} [\Lambda_1 - \Lambda_2] \xrightarrow{\textcolor{red}{1}} [-\Lambda_1]$$

Checked for finite types (currently work in progress)

We are now looking for an abstract property on the crystal
that ensures that everything works

- 1_λ stays minimal when dots are put on certain strands \rightsquigarrow get $y^a 1_\lambda$
- Done!

Let us sand

The (conjectural) picture for all types – second example

$C_e^{(1)}$

$C_3^{(1)}$

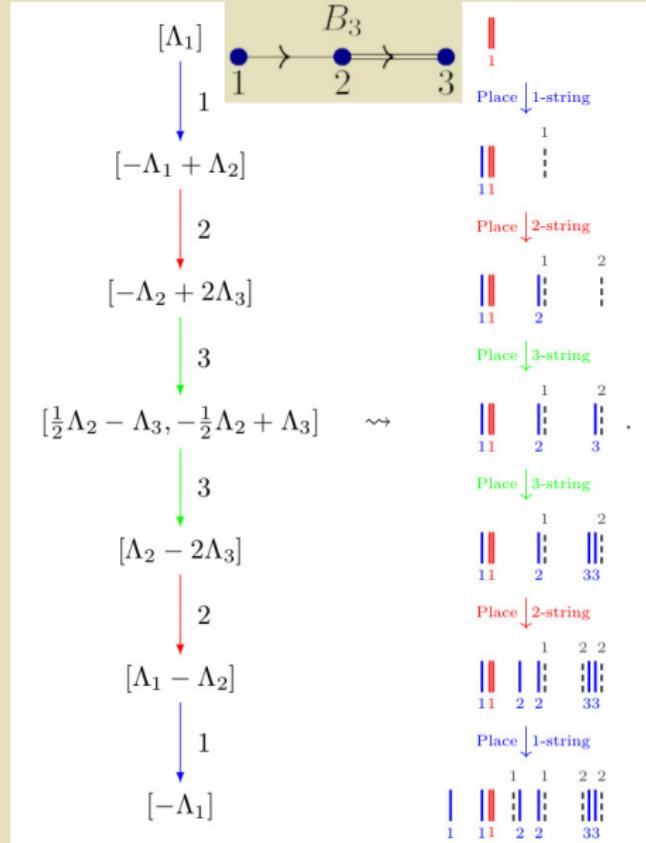

► Assume

► Place st

► 1_λ is m

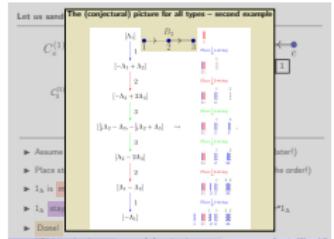

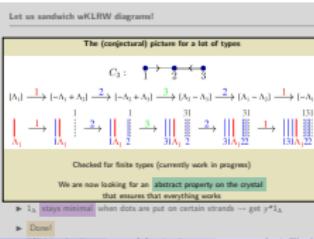

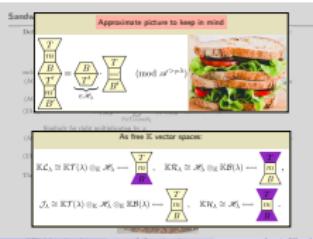

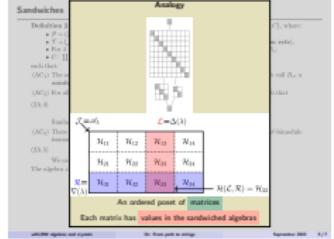

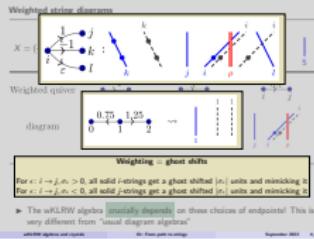

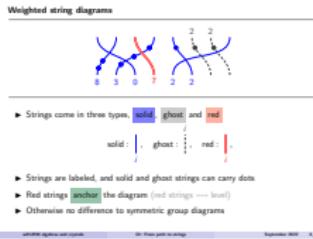

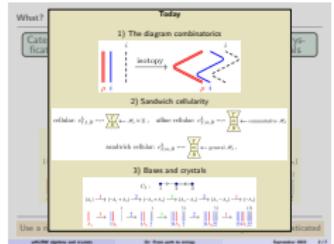

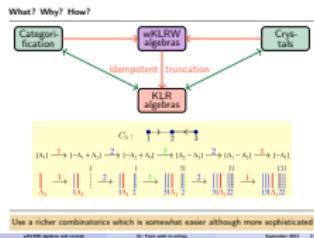

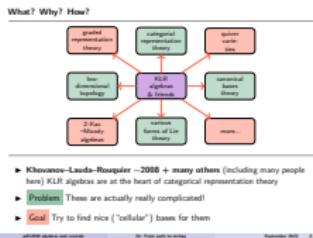

► 1_λ stay

► Done!

Wrap up

- ▶ wKLRW algebras generalize KLR algebras and friends
 - ▶ They have a build in distance
 - ▶ Most properties can be described using distance
 - ▶ Most properties are type-independent
 - ▶ Some properties are (in some form) type-independent
- ▶ Our dim calculations for the sandwich cellular basis match with the formulas of **Hu-Shi ~2021** in the special cyclotomic KLR case
- ▶ 1_λ is minimal with respect to placing the strings to the right
- ▶ 1_λ stays minimal when dots are put on certain strands \rightsquigarrow get $y^a 1_\lambda$
- ▶ Done!

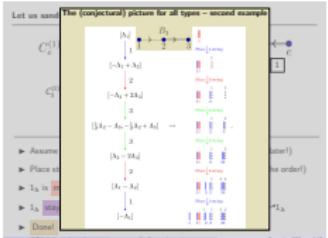

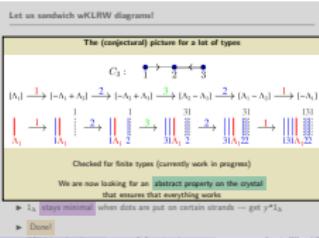

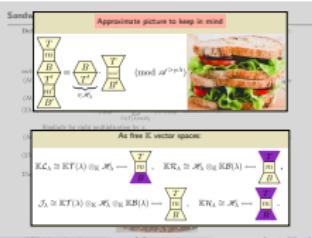

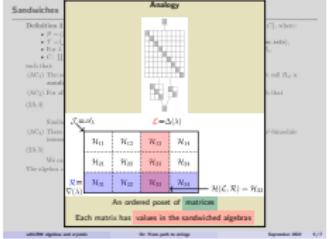

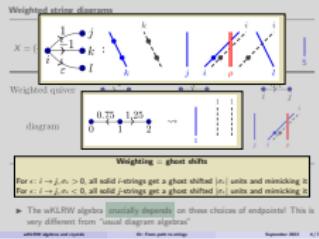

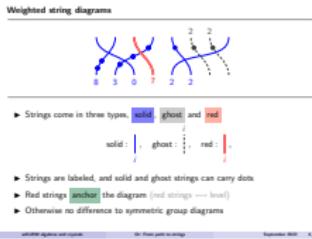

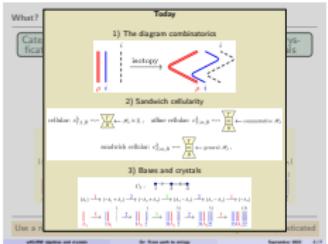

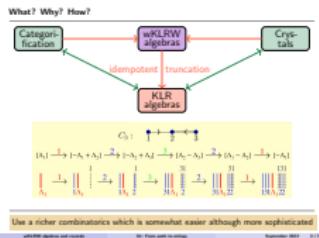

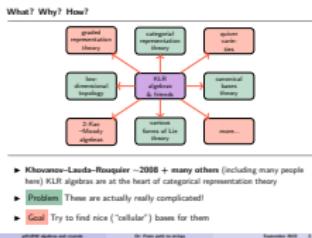

There is still much to do...

wKLRW algebras and crystals

Or: From path to strings
